

ABSTRACT

5 The present invention provides an apparatus, system and method of peak-
to-average reduction of an oversampled signal for a digital communication
system. Peak detection 504 and width measurement 504 are advantageously
combined in which a peak portion or multiple peak portions of an input signal that
exceeds a predetermined threshold is detected and a width of the peak portion is
10 determined. The peak detection and width measurement are further combined
with a novel variable width shape generation methodology 506 in which a
variable width shaping response is applied 510 to the peak portion responsive to
the peak portion width. Additionally, a novel receiver technique 1390 can be
included to reduce or eliminate the upstream BER impact using downstream
15 oversampled shaping.
